

Lab 3 EDA Reflection

Steven Ford

The first thing I noticed in this lab was the way that data will preview the rows and then list the features i.e. columns. From class, I learned that this is our x and y variables with which the program can create visualizations of the data and I can imagine the numbers and categories on a spreadsheet. This helps me understand what the program is doing and saying with a more familiar reference (reading a spreadsheet).

The next section was a summary of statistics for the numerical features. The takeaway for me here was when comparing the lists of numbers with a data visualization the charts and graphs provide clearer insights that are more difficult to denote from this list of numbers.

Aside from the insights straight from the lab and data themselves, I discovered a couple things with Gemini in Google Colab. The first was when I opened the file with Colab, the code was on the same line and not running properly but I was able to in the same window ask Gemini to trouble shoot it and it suggested the proper spacing for the code to run right. This took the guess work out of me trying to divide it myself and reduced time working.

The last insight was when I was writing my own code for the embarked/survival chart and the survived/fare graph was I only started to write the first word of the code and the rest of the program was suggested out for me automatically through Gemini. Since I've gotten into programming and AI, I've seen online how programmers say you don't even need to know coding and use Claude for everything, and I can see how that's possible now. Though I still want to learn coding I'm just intrigued to see how it can work with very little coding knowledge.
